Abstract

Definitions for a local pressure in an inhomogeneous fluid are considered for both equilibrium and local equilibrium states. Thermodynamic and mechanical (hydrodynamic) contexts are reconciled. Remaining problems and uncertainties are discussed.

I. INTRODUCTION

The global pressure for equilibrium systems is well-defined within statistical mechanics, both quantum and classical. For extensive systems the definitions for different ensembles are equivalent. Here the grand canonical ensemble will be chosen for such representations, characterized by an inverse temperature $\beta$ and activity $\nu$. The global pressure is then proportional to the grand potential which defines all thermodynamic properties of the system. Its form is obtained from variations of the grand potential with respect to volume, leading to the equilibrium average of a specific operator equivalent to the familiar virial equation.

For the special case of inhomogeneous equilibrium states for systems with an external potential $v^{\text{ext}}(r)$ the effective activity $\nu(r) \equiv \nu - \beta v^{\text{ext}}(r)$ varies locally so it is appropriate to define an associated local thermodynamics. The first objective here is to explore how to define a local thermodynamic pressure $p^{e}(r, \beta \mid \nu)$ whose spatial integral is the global pressure. The notation indicates that the local pressure depends on the space point $r$, the inverse temperature $\beta$, and is a functional of $\nu(r)$. It is straightforward to identify a local operator whose ensemble average integrates to the global virial equation, defining such a local pressure. However, it is not unique since any contribution whose integral vanishes can be added. Additional constraints are needed.

A conceptually different notion of pressure is obtained from the average momentum flux of the inhomogeneous equilibrium fluid, or pressure tensor $p^{e}_{ij}(r, \beta \mid \nu)$. Local conservation of momentum at equilibrium leads to a force balance equation relating the gradient of that pressure tensor to the applied external force. This approach has an extensive history in the classical description of interfaces and surface tension. Derivation of the conservation law from the underlying Heisenberg dynamics provides the form of the operator whose average gives the pressure tensor. It does not explicitly exploit the grand potential or any thermodynamics other than the stationarity of the equilibrium state. While the local thermodynamic pressure is defined only indirectly from the global pressure, the pressure tensor is inherently a local property. However, this method only provides the divergence of the pressure tensor and the latter is therefore not unique. Consequently the related scalar pressure $p^{e}_{m}(r, \beta \mid \nu) \equiv p^{e}_{ii}(r, \beta \mid \nu)/3$ also is not unique (here and below a summation over repeated indices is implied). The pressure obtained from the pressure tensor will be referred to as the hydrodynamic or mechanical pressure as it appears in the macroscopic...
conservation equations. Clearly, it is desirable that the thermodynamic and hydrodynamic pressures should be the same for consistent representations of the stationary states. It is expected that the uncertainties in each can be exploited to assure this equivalence.

Two cases are considered here, the inhomogeneous equilibrium states described above, and their generalization to local equilibrium states. The latter differ in the sense that the inverse temperature can be spatially varying, \( \beta = \beta(\mathbf{r}) \), in addition to the activity \( \nu(\mathbf{r}) \). For equilibrium states it is shown that the uncertainty in the thermodynamic pressure can be removed by adding a contribution that equates it to the hydrodynamic pressure.

The same objective arises in the more general context of non-stationary local equilibrium states of hydrodynamics. The associated ensemble is similar to the equilibrium ensemble. A “thermodynamics” for this state can be defined from the associated grand potential and an associated local pressure identified\(^{10,11}\). However, in this case, for spatially varying \( \beta(\mathbf{r}) \), there is no longer the flexibility to modify the thermodynamic local pressure to be equal to that from the local equilibrium average of the stress tensor. Consequently, it would seem that the equation of state for hydrodynamics is not the same as that for local equilibrium thermodynamics. The precise difference is identified below. Unfortunately, this implies that the equivalence chosen for the strict equilibrium noted above is not recovered from the hydrodynamic equations for their stationary limit.

This paradox is resolved by exploiting the uncertainty in the pressure tensor. A divergenceless additional contribution to the average momentum flux can be chosen such that the local pressure associated with the new momentum flux agrees with the thermodynamic pressure. In this way thermodynamic and mechanical concepts are reconciled.

The analysis here is based in quantum statistical mechanics so that all average properties have an associated underlying operator representing them. The calculation of their averages is not discussed but the connection to density functional theory methods is indicated. An alternative approach is to postulate an average pressure tensor and verify that it yields the required macroscopic force balance equation. This has been described by Percus\(^5\) for the inhomogeneous equilibrium fluid. His pressure tensor is entirely characterized by the thermodynamic free energy density. It is described in Supporting Information S.3 and the associated pressure is identified.

The primary importance of this investigation of equivalence is for the local equilibrium states of hydrodynamics. In that case both concepts of the pressure occur. The first is as a
functional relationship between the fundamental conserved number, energy, and momentum densities and their conjugate fields activity, temperature, and flow velocity. This functional relationship is the thermodynamics of the local equilibrium grand potential, or thermodynamics pressure. The second occurrence is through the average momentum flux, comprised as a reference local equilibrium average and a dissipative component. Only the reference contribution is considered here and is referred to as the average mechanical pressure tensor here. It is a functional of the conjugate fields. Hence the equivalence of the thermodynamic and mechanical pressures is a necessary condition for the hydrodynamic equations to provide a closed local macroscopic description, regardless of the choice for the dissipative component (e.g., Navier-Stokes or far from equilibrium).

At this point it is appropriate to characterize the context by noting related topics not bearing directly on the question of equivalence. The lack of uniqueness for the mechanical pressure tensor is well-known; for early references see Refs. 6–9. Most of these studies do not make explicit the required equivalence with thermodynamic pressure. An exception is one demonstration that the Harasima choice gives the wrong pressure in cylindrical coordinates. This is resolved in a recent work for cylindrical geometry by synthesizing the Irving and Kirkwood and Harasima expressions for different coordinates. Another definition of the local thermodynamic pressure closer to that given here does not make any connection to the various choices for the mechanical pressure tensor. In summary, the work here is complementary to this important body of work by relating the two different studies of thermodynamic pressure and mechanical pressure tensor. Further comment is given in the final section where measurement by simulation is briefly discussed.

The local equilibrium thermodynamics considered here describes a reference state for real non-equilibrium systems. In the context of information entropy it provides the optimal representation in terms of the given exact average local conserved densities. The latter must be provided from some detailed exact theory (e.g., Liouville-von Neumann equation). The grand potential associated with the local equilibrium ensemble provides the “equation of state” for generating conjugate variables like temperature and activity, and is the direct analogue of equilibrium thermodynamics. To further clarify the context it is noted that the current work does not relate to the general fields of “non-equilibrium thermodynamics” nor “extended thermodynamics”. The former is an attempt to discover universal fundamental principles, similar to those of equilibrium thermodynamics (e.g., a generalized second
law, entropy), to govern the dissipative dynamics of macroscopic properties. Extended irreversible thermodynamics takes as the macroscopic fields the usual local conserved fields plus the dissipative fluxes of energy and momentum. The conservation laws of ordinary hydrodynamics must then be supplemented with unknown additional equations for the dissipative fluxes. If the latter could be given in terms of the conserved fields this would not be necessary, so in a sense extended hydrodynamics is a tool to discover those forms. The local equilibrium thermodynamics considered here is not a theory, such as those sought above, but rather an exact functional relationship among two equivalence classes of fields — there is no entropy production nor inherent dissipation beyond that of the input fields. While it represents general non-equilibrium states, it is not predictive without the hydrodynamic equations themselves (for an exact formulation of the latter see Ref. 10).

II. LOCAL PRESSURE FOR AN INHOMOGENEOUS FLUID AT EQUILIBRIUM

Consider first a system of $N$ particles in a large volume $V$ with Hamiltonian

$$H_N = H_N + \sum_{\alpha=1}^{N} v_{\alpha}^{\text{ext}}(q_{\alpha}),$$

where $v_{\alpha}^{\text{ext}}(q_{\alpha})$ is an external potential coupling to the particle with position operator $q_{\alpha}$, and the isolated system Hamiltonian $H_N$ is

$$H_N = \sum_{\alpha=1}^{N} \frac{p_{\alpha}^2}{2m} + \frac{1}{2} \sum_{\alpha \neq \sigma=1}^{N} U_N(|q_\alpha - q_\sigma|).$$

Here $U_N(|q_\alpha - q_\sigma|)$ is a pair potential for particles $\alpha$ and $\sigma$, and $p_\alpha$ is the momentum operator for particle $\alpha$. At equilibrium with inverse temperature $\beta$ and activity $\nu$ the average of a property characterized by an operator $X_N$ is given in the grand canonical ensemble by

$$\langle X \rangle^e \equiv \sum_{N} \text{Tr}^{(N)} X_N \rho_N^e, \quad \rho_N^e = e^{-Q^e(\beta, V|\nu)} e^{-\left(\beta H_N - f d\nu(r)n(r)\right)}.$$  

The external potential has been combined with the activity to define a local activity $\nu(r)$

$$\nu(r) \equiv \nu - \beta v_{\alpha}^{\text{ext}}(r),$$

and $n(r)$ is the number density operator

$$n(r) = \sum_{\alpha=1}^{N} \delta(r - q_{\alpha}).$$
The notation \( Y(\beta, V \mid \nu) \) here and below denotes a function of \( \beta, V \) and a functional of \( \nu(r) \). The normalization function \( Q^e(\beta, V \mid \nu) \) is known as the grand potential and is chosen such that \( \langle 1 \rangle^e = 1 \)

\[
Q^e(\beta, V \mid \nu) = \ln \sum_N T_{\beta N} e^{-(\beta H_N - \int d\nu(r) n(r))}. \tag{6}
\]

It determines the complete thermodynamics for the system through the definition of the global pressure

\[
\beta P^e(\beta \mid \nu) V = Q^e(\beta, V \mid \nu). \tag{7}
\]

For a sufficiently large volume \( Q^e(\beta, V \mid \nu) \) is extensive (proportional to \( V \)) so the pressure is independent of the volume. Then an equivalent form for (7) is

\[
\beta P^e(\beta \mid \nu) = \left. \frac{\partial Q^e(\beta, V \mid \nu)}{\partial V} \right|_{\beta, \nu}. \tag{8}
\]

The volume derivative can be calculated directly (e.g., using length scaling) to get

\[
P^e(\beta \mid \nu) = \frac{1}{3V} (2 \langle K \rangle^e + \langle V \rangle^e), \tag{9}
\]

where \( K \) is the kinetic energy operator and \( V \) is the virial operator (for the internal forces)

\[
K = \sum_{\alpha=1}^N \frac{1}{2m} p^2_{\alpha j}, \quad V = \frac{1}{2} \sum_{\alpha \neq \gamma = 1}^N (\mathbf{q}_\gamma - \mathbf{q}_\alpha) : \mathbf{F}_{\alpha \gamma}(|\mathbf{q}_\alpha - \mathbf{q}_\gamma|). \tag{10}
\]

It is seen that (9) is the usual virial equation for the global (intrinsic) pressure, confirming the consistency of the thermodynamic and mechanical concepts of global pressure.

The objective now is to identify an associated local density pressure. It is done by defining a local density for the grand potential in (7)

\[
\int d\mathbf{r} \beta p^e(\mathbf{r}, \beta \mid \nu) = Q^e(\beta, V \mid \nu). \tag{11}
\]

Accordingly, \( V^{-1} p^e(\mathbf{r}, \beta \mid \nu) \) is the local density for the global pressure

\[
P^e(\beta \mid \nu) \equiv \frac{1}{V} \int d\mathbf{r} p^e(\mathbf{r}, \beta \mid \nu). \tag{12}
\]

One choice to identify it is to replace the operators \( K \) and \( V \) in (11) by associated local densities

\[
p^e_0(\mathbf{r}, \beta \mid \nu) = \frac{1}{3} \langle 2K_0(\mathbf{r}) + V_0(\mathbf{r}) \rangle^e, \tag{13}
\]
where
\[ K_0(r) = \frac{1}{4m} \sum_{\alpha=1}^{N} [p^2_{\alpha}, \delta(r - q_{\alpha})]_+ \] (14)

\[ Y_0(r) = \frac{1}{2} \sum_{\alpha \neq \sigma=1}^{N} F_{\alpha \sigma i} (|q_{\alpha} - q_{\sigma}|) (q_{\sigma} - q_{\alpha}) \delta(r - q_{\alpha}). \] (15)

The brackets \([a, b]_+\) denote an anti-commutator. It is required in (14) to assure that \(K_0(r)\) is Hermitian. More generally, the local pressure can be expressed as
\[ p^e(r, \beta | \nu) = p^e_0(r, \beta | \nu) + \Delta p^e_0(r, \beta | \nu) \] (16)

where \(\Delta p^e_0(r, \beta | \nu)\) is any functional whose volume integral vanishes.
\[ \int d\mathbf{r} \Delta p^e(r, \beta | \nu) = 0. \] (17)

To suggest an alternative choice for \(p^e(r, \beta | \nu)\) consider the exact microscopic conservation law for the momentum density operator \(p_i(r, t)\) (see Supporting Information S.1)
\[ \partial_t p_i(r, t) + \partial_j t_{ij}(r, t) = -n(r, t) \partial_i v^{\text{ext}}(r, t), \] (18)

where the momentum density operator is
\[ \mathbf{p}(r, t) = \frac{1}{2} \sum_{\alpha=1}^{N} [p_{\alpha}(t), \delta(r - q_{\alpha}(t))]_+ \] (19)

and the momentum flux is
\[ t_{ij}(r, t) = \frac{1}{4m} \sum_{\alpha=1}^{N} [p_{i\alpha}(t), [p_{j\alpha}(t), \delta(r - q_{\alpha}(t))]_+]_+ \]
\[ + \frac{1}{2} \sum_{\alpha \neq \sigma=1}^{N} F_{\alpha \sigma i} (|q_{\alpha}(t) - q_{\sigma}(t)|) \mathcal{D}_j(r, q_{\alpha}(t), q_{\sigma}(t)). \] (20)

The operator \(\mathcal{D}_j(r, q_{\alpha}(t), q_{\sigma}(t))\) is given by
\[ \mathcal{D}_j(r, q_1, q_2) \equiv \int_{\mathcal{C}} d\lambda \frac{dx_j(\lambda)}{d\lambda} \delta(r - \mathbf{x}(\lambda)), \quad \mathbf{x}(\lambda_1) = q_1, \quad \mathbf{x}(\lambda_2) = q_2. \] (21)

Here \(\mathcal{C}\) is an arbitrary continuous path connecting \(\mathbf{x}(\lambda)\) between \(\lambda_1\) and \(\lambda_2\). (Further comment on the choice is given in Supporting Information S.2.)

Since the equilibrium ensemble is stationary, the equilibrium average of (18) gives the stationary equilibrium force balance equation
\[ \partial_j \langle t_{ij}(r) \rangle^e = -\langle n(r) \rangle^e \partial_i v^{\text{ext}}(r) \] (22)
This is the expected local stability condition. A mechanical pressure can be associated with the average momentum flux according to

\[ p_m^e (r, \beta | \nu) \equiv \frac{1}{3} \langle t_{ii}(r) \rangle^e \]  

(23)

Note that (20) implies

\[ \frac{1}{V} \int dr \frac{1}{3} \langle t_{ii}(r) \rangle^e = \frac{1}{3V} (2 \langle K \rangle^e + \langle V \rangle^e) = P^e (\beta | \nu) \]  

(24)

where the last equality follows from (9). Use has been made of the identity

\[ \int dr D(r, q_\alpha, q_\gamma) = q_\alpha - q_\gamma. \]  

(25)

The left side of (24) suggests an alternative choice for the definition of a local pressure in (12)

\[ p^e (r, \beta | \nu) = p_m^e (r, \beta | \nu) = \frac{1}{3} \langle t_{ii}(r) \rangle^e . \]  

(26)

This definition has a mechanical origin, without direct reference to the grand potential or thermodynamics.

The two choices \( p_0^e (r, \beta | \nu) \) and \( p_m^e (r, \beta | \nu) \) are clearly different, but both yield the thermodynamic global pressure. The choice \( p^e (r, \beta | \nu) = p_m^e (r, \beta | \nu) \) for the local pressure in (12) is clearly the desirable one as it assures the mechanical balance equation is consistent with thermodynamics.

Since \( t_{ii}(r) \) has a precise microscopic origin, this provides a local microscopic basis for the pressure

\[ p^e (r, \beta | \nu) = \frac{1}{3} (2 \langle K(r) \rangle^e + \langle V(r) \rangle^e) \]  

(27)

with

\[ K(r) = \frac{1}{8m} \sum_{\alpha=1}^{N} \left[ p_{i\alpha}, [p_{i\alpha}, \delta (r - q_\alpha)]_+ \right]_+ \]  

(28)

and

\[ V(r) = \frac{1}{2} \sum_{\alpha \neq \sigma = 1}^{N} F_{\alpha\sigma} (|q_\alpha - q_\sigma|) D_i (r, q_\alpha, q_\sigma) . \]

This is the desired result.

It is seen that while the global pressure is the same for \( p^e (r, \beta | \nu) \) and \( p_0^e (r, \beta | \nu) \), the local pressures differ in their microscopic realizations.
\[ K(\mathbf{r}) = K_0(\mathbf{r}) + \frac{\hbar^2}{8m} \nabla^2 n(\mathbf{r}) , \]  

\[ V(\mathbf{r}) = V_0(\mathbf{r}) + \frac{1}{2} \sum_{\alpha \neq \sigma = 1}^{N} F_{\alpha \sigma} \left( |q_\alpha - q_\sigma| \right) \left[ \mathcal{D}_i(\mathbf{r}, q_\alpha, q_\sigma) - (q_\sigma - q_\alpha) \delta(\mathbf{r} - q_\alpha) \right] . \]  

To get (29) use has been made of the identity

\[ \frac{1}{2m} \sum_{\alpha} p_{\alpha i} \delta(\mathbf{r} - q_\alpha) p_{\alpha i} = K_0(\mathbf{r}) + \frac{\hbar^2}{4m} \nabla^2 n(\mathbf{r}) . \]  

The dependence on \( \hbar \) has been made explicit in (29) and (31) to emphasize this is a purely quantum effect. The identification of the local pressure in terms of the average momentum flux is a common definition. What is new here is its identification as the thermodynamic local pressure for the grand ensemble.

The local pressure \( p^e_m(\mathbf{r}, \beta | \nu) \) is more sensitive to spatial variations of the inhomogeneous state than \( p^e_0(\mathbf{r}, \beta | \nu) \). In fact \( p^e_0(\mathbf{r}, \beta | \nu) \) results from it by a leading order Taylor series approximation, e.g.

\[ \mathcal{D}_i(\mathbf{r}, q_\alpha, q_\sigma) = (q_\sigma - q_\alpha) \delta(\mathbf{r} - q_\alpha) + \int_{\lambda_2}^{\lambda_1} d\lambda \frac{dx_i(\lambda)}{d\lambda} \left[ \delta(\mathbf{r} - x(\lambda)) - \delta(\mathbf{r} - q_\alpha) \right] \]

\[ \simeq (q_\sigma - q_\alpha) \delta(\mathbf{r} - q_\alpha) . \]  

This gives \( V(\mathbf{r}) \simeq V_0(\mathbf{r}) \) and \( p^e_m(\mathbf{r}, \beta | \nu) \simeq p^e_0(\mathbf{r}, \beta | \nu) \). This leading order approximation is justified only in the context of states that have smooth spatial variations over distances of the order of the force range. For extreme conditions, such as occur for warm, dense matter states it would seem that the form (20) must be used for the momentum flux.

In summary, two definitions for a local pressure have been identified, \( p^e_0(\mathbf{r}, \beta | \nu) \) and \( p^e_m(\mathbf{r}, \beta | \nu) \). Each has been identified in terms of the average of an underlying microscopic operator. They provide the same global thermodynamics in the sense that both of their volume integrals yield \( P^e(\beta | \nu) \). However, at the local level they differ by \( \Delta p^e_m(\mathbf{r}, \beta | \nu) \), identified from (29) - (31). The choice of \( p^e(\mathbf{r}, \beta | \nu) = p^e_m(\mathbf{r}, \beta | \nu) \) for the thermodynamic pressure is made on the basis of equating thermodynamic and mechanical definitions.

So far only the scalar local pressure has been considered. There is no thermodynamic route to define a local pressure tensor for an inhomogeneous fluid at equilibrium (see however Supporting Information S.3). Instead it is identified from (22).
\[ p_{ij}^e (r, \beta | \nu) \equiv \langle t_{ij} (r) \rangle^e . \]  

By construction it has the form

\[ p_{ij}^e (r, \beta | \nu) = \frac{1}{3} p^e (r, \beta | \nu) \delta_{ij} + \widetilde{p}_{ij}^e (r, \beta | \nu) , \]  

(with \( \widetilde{p}_{ij}^e \) is its traceless part) and satisfies the force balance equation

\[ \partial_j p_{ij}^e (r, \beta | \nu) = - \langle n(r) \rangle \partial_i v^{\text{ext}}(r) . \]  

In the next section, attempts to extend the equivalence of thermodynamic and mechanical concepts to local equilibrium states in the same way lead to difficulties due to the spatial variations of \( \beta(r, t) \).

III. LOCAL HYDRODYNAMIC PRESSURE

Consider now a general non-equilibrium state. The macroscopic hydrodynamic equations have their origins in averages of the underlying microscopic conservation laws for number density, energy density, and momentum density, \( \{ \langle n(r, t) \rangle , \langle e(r, t) \rangle , \langle p(r, t) \rangle \}^{10,11,22} \). In particular the hydrodynamic equation resulting from the conservation law for the momentum density follows from the non-equilibrium average of \( \langle \rangle \)

\[ \partial_t \langle p_i (r, t) \rangle + \partial_j \langle t_{ij} (r, t) \rangle = - \langle n(r, t) \rangle \partial_i v^{\text{ext}}(r, t) , \]  

where the brackets now denote a non-equilibrium average

\[ \langle X (t) \rangle \equiv \sum_N Tr^{(N)} X_N \rho_N (t) , \]  

and \( \rho_N (t) \) is a solution to the Liouville - von Neumann equation. Traditionally, the momentum density is expressed in terms of a local flow velocity \( u(r, t) \) defined by

\[ \langle p(r, t) \rangle \equiv m \langle n(r, t) \rangle u(r, t) \]  

and \( \langle \rangle \) is written in terms of the momentum flux in the local rest frame

\[ \langle t_{ij} (r, t) \rangle = m \langle n(r, t) \rangle u_i (r, t) u_j (r, t) + \langle t_{0ij} (r, t) \rangle . \]
Here the rest frame momentum flux \( t_{0ij}(\mathbf{r}, t) \) has the same form as (20) with the particle momenta in the rest frame, \( p_{i\alpha}(t) \rightarrow p_{i\alpha}(t) - mu_i(q_\alpha(t), t) \). Then the momentum conservation law takes the form

\[
D_t u_i(\mathbf{r}, t) + \partial_j \langle t_{0ij}(\mathbf{r}, t) \rangle = -\langle n(\mathbf{r}, t) \rangle \partial_i v_{ext}(\mathbf{r}, t),
\]

with the material derivative \( D_t = \partial_t + \mathbf{u}(\mathbf{r}, t) \cdot \nabla \). In this way the purely convective contributions have been made explicit.

It remains to calculate the rest frame momentum flux \( \langle t_{0ij}(\mathbf{r}, t) \rangle \). To do so, the solution to the Liouville - von Neumann equation is separated into a reference local equilibrium state, \( \rho_N^{\ell} \), and its remainder \( \Delta N \)

\[
\rho_N(t) = \rho_N^{\ell}[y(t)] + \Delta N(t).
\]

The reference local equilibrium state is chosen to be entirely determined by a set of conjugate fields \( \{y(t)\} \) in one-to-one correspondence with the macroscopic conserved fields \( \{\langle n(\mathbf{r}, t) \rangle, \langle e(\mathbf{r}, t) \rangle, \langle p(\mathbf{r}, t) \rangle\} \}. This correspondence is defined by the requirements that the reference state yield the exact averages for the local conserved fields

\[
\begin{align*}
\langle n(\mathbf{r}, t) \rangle_{\ell} &\equiv \langle n(\mathbf{r}, t) \rangle, \\
\langle e(\mathbf{r}, t) \rangle_{\ell} &\equiv \langle e(\mathbf{r}, t) \rangle, \\
\langle p(\mathbf{r}, t) \rangle_{\ell} &\equiv \langle p(\mathbf{r}, t) \rangle,
\end{align*}
\]

where the superscript \( \ell \) denotes a reference ensemble average, \( \bar{A} = \langle A; \rho \rangle \). The left sides of these equations are functionals of the conjugate fields while the right sides are the fields of the local conservation laws. In this way the conjugate fields \( \{y(t)\} \) are functionals of the average conserved fields, and vice versa by inversion. The reference state therefore has the exact average values for the conserved fields by construction.

A choice for \( \rho_N^{\ell} \) with these properties is the local equilibrium ensemble 11,22

\[
\rho_N^{\ell}[y(t)] = e^{-\eta[y(t)]}, \quad \eta[y(t)] = \mathcal{Q}^{\ell}[y(t)] + \int d\mathbf{r} \psi_\kappa(\mathbf{r}) y_\kappa(\mathbf{r}, t),
\]

\[
\mathcal{Q}^{\ell}[y(t)] = \ln \sum_N T_Y^{(N)} e^{-\int d\mathbf{r} \psi_\kappa(\mathbf{r}) y_\kappa(\mathbf{r}, t)}
\]

where \( \psi_\kappa(\mathbf{r}) \) are the operators representing the local conserved number density, energy density, and momentum density

\[
\{\psi_\kappa(\mathbf{r})\} \equiv \{n(\mathbf{r}), e(\mathbf{r}), p(\mathbf{r})\}.
\]
and \(y_\kappa(r,t)\) are the conjugate fields,

\[
\{y(r,t)\} \leftrightarrow \left\{ \left[ -\nu(r,t) + \frac{\beta(r,t)}{2} mu^2(r,t) \right], \beta(r,t), -\beta(r,t)u(r,t) \right\} .
\]  

(46)

It is interesting to note that this local equilibrium ensemble is also the “best choice” in the sense that it maximizes the information entropy for the given values of the conservative fields\(^{15-17}\). In Ref.\(^{11}\) it is also called the “relevant” ensemble.

Accordingly, the average rest frame momentum flux \(\langle t_{0ij}(r,t) \rangle\) of (39) has two contributions. One is from the reference local equilibrium ensemble \(\rho_N\) and one from the remainder in (41)

\[
\langle t_{0ij}(r,t) \rangle = \sum_N Tr^{(N)} t_{0ij}(r) \rho_N(y(t)) + \sum_N Tr^{(N)} t_{0ij}(r) \Delta_N(t)
\]

\[
\equiv \overline{t_{0ij}} (r | y(t)) + \delta \langle t_{0ij}(r,t) \rangle
\]  

(47)

It is shown elsewhere\(^{10,11}\) that the second term of (47) describes the dissipative processes of the system while the first term characterizes the “perfect fluid” (e.g. Euler) dynamics. The latter is entirely determined by its functional dependence on the conjugate fields and reduces to the equilibrium pressure tensor of the last section in the case of uniform \(\beta(r,t)\).

In the following attention will be restricted to \(\overline{t_{0ij}} (r | y(t))\) and its possible relationship to an underlying “local equilibrium thermodynamics.”

For the purpose of calculating averages in the rest frame, the macroscopic velocity dependence can be eliminated so the conjugate fields simplify to

\[
\{y(r)\} \leftrightarrow \{-\nu(r), \beta(r), 0\} .
\]  

(48)

Also, the dependence of these fields on time has been suppressed for simplicity here and below. The hydrodynamic (mechanical) pressure and pressure tensor are defined in terms of the momentum flux as in the previous section

\[
p^\ell_{ij}(r | \beta, \nu) \equiv \overline{t_{0ij}} (r | \beta, \nu),
\]  

(49)

\[
p^\ell_m(r | \beta, \nu) \equiv \frac{1}{3} \overline{t_{0ii}} (r | \beta, \nu).
\]  

(50)

Since the functional form of the operator \(t_{ij}(r,t)\) in (52) is the same for both equilibrium and non-equilibrium states, the local pressure here is still given by (27) with only the definition of the average changed

\[
p^\ell_m(r | \beta, \nu) = \frac{1}{3} \left( 2K(r) + V(r) \right).
\]  

(51)

12
Next, a thermodynamics associated with the local equilibrium state is defined in analogy to strict equilibrium via the normalization function $Q^\ell[y]$ of (44). As noted above the average velocity field can be transformed to zero so the energy $e(r)$ is also in the local rest frame. Then (44) becomes

$$Q^\ell[\beta, \nu] = \ln \sum_N Tr^{(N)} e^{-\int dr [\beta(r)e(r) - \nu(r)n(r)]}.$$  

(52)

In analogy to (7) and (8), a local equilibrium pressure can be defined by

$$\int dr \beta r p^\ell(r | \beta, \nu) \equiv Q^\ell[\beta, \nu],$$  

(53)

or for extensive systems

$$\frac{1}{V} \int dr \beta r p^\ell(r | \beta, \nu) = \left. \frac{\partial Q^\ell[\beta, \nu]}{\partial V} \right|_{\beta, \nu}. $$  

(54)

Carrying our the volume derivative leads to

$$\left. \frac{\partial Q^\ell[\beta, \nu]}{\partial V} \right|_{\beta, \nu} = \frac{1}{3V} \sum_{\alpha=1}^N \frac{1}{2m} \left[ p_{\alpha j}^2, \beta(q_\alpha) \right]_+ \bigg|_{y(t)} + \frac{1}{2} \sum_{\alpha \neq \gamma=1}^N \beta(q_\alpha)(q_\gamma - q_\alpha) \cdot F_{\alpha \gamma}(|q_\alpha - q_\gamma|) \bigg|_{y(t)}$$  

(55)

$$= \frac{1}{V} \int dr \beta r \left[ \frac{1}{3} \left[ 2K_0(r)^\ell + V_0(r)^\ell \right] \right]$$  

(56)

where $K_0(r)$ and $V_0(r)$ are given by (14) and (15). Therefore, (54), or equivalently (53), gives the identification

$$Q^\ell[\beta, \nu] = \int dr \beta r p_0^\ell(r | \beta, \nu),$$  

(57)

with

$$p_0^\ell(r | \beta, \nu) = \frac{1}{3} \left[ 2K_0(r)^\ell + V_0(r)^\ell \right].$$  

(58)

This is not the same as the hydrodynamic pressure of (51), $P^\ell(r, \beta | \nu)$. Their volume integrals are the same

$$P^\ell[\beta, \nu] \equiv \frac{1}{V} \int dr p_0^\ell(r | \beta, \nu) = \frac{1}{V} \int dr p_m^\ell(r | \beta, \nu)$$  

(59)

but only $p_0^\ell(r | \beta, \nu)$ provides the local density for the grand potential

$$Q^\ell[\beta, \nu] = \int dr \beta r p_0^\ell(r | \beta, \nu) \neq \int dr \beta r p_m^\ell(r | \beta, \nu).$$  

(60)
This can be stated in an equivalent way. Using (29) and (30) the relationship is

$$p^\ell_m (\mathbf{r} | \beta, \nu) = p^\ell_0 (\mathbf{r} | \beta, \nu) + \Delta p^\ell_0 (\mathbf{r} | \beta, \nu)$$  \hspace{1cm} (61)

$$\Delta p^\ell_0 (\mathbf{r} | \beta, \nu) = \frac{\hbar^2}{12m} \nabla^2 \pi^\ell (\mathbf{r}) + \frac{1}{6} \sum_{\alpha \neq \sigma = 1}^N F_{\alpha \sigma} (|q_\alpha - q_\sigma|) [D_i (\mathbf{r}, q_\alpha, q_\sigma) - (q_\sigma - q_\alpha) \delta (\mathbf{r} - q_\alpha)] \ .$$  \hspace{1cm} (62)

Planck’s constant has been restored in (62) to make explicit the fact that this term has a purely quantum origin. The local pressures differ for strongly inhomogeneous states, but are the same globally

$$\int d\mathbf{r} \Delta p^\ell_0 (\mathbf{r} | \beta, \nu) = 0. \hspace{1cm} (63)$$

However, in contrast to the strict equilibrium case of the last section they do not both give the grand potential due to the appearance of $\beta(q_\alpha)$ in (55)

$$\int d\mathbf{r} \beta (\mathbf{r}) \Delta p^\ell_0 (\mathbf{r} | \beta, \nu) \neq 0. \hspace{1cm} (64)$$

Thus the hydrodynamic local pressure, $p^\ell_m (\mathbf{r} | \beta, \nu)$, does not have the expected relationship to thermodynamics.

The seeming paradox now is that the stationary solution to the hydrodynamic equations is (35)

$$\partial_j p^\ell_{ij} (\mathbf{r}, \beta | \nu) = - \langle n(\mathbf{r}) \rangle \partial_i v^{\text{ext}} (\mathbf{r}), \hspace{1cm} (65)$$

$$p^\ell_{ij} (\mathbf{r}, \beta | \nu) = \frac{1}{3} p^\ell_m (\mathbf{r}, \beta | \nu) \delta_{ij} + \tilde{p}^\ell_{ij} (\mathbf{r}, \beta | \nu), \hspace{1cm} (66)$$

but the corresponding pressure $p^\ell_m (\mathbf{r}, \beta | \nu)$ is not the thermodynamic local pressure $p^\ell_0 (\mathbf{r} | \beta, \nu)$ even in the limit of uniform $\beta$. The hydrodynamic stationary state is not the thermodynamic state.

**IV. REVISED MOMENTUM FLUX AND HYDRODYNAMIC PRESSURE**

While there is no flexibility in the choice $p^\ell_0 (\mathbf{r} | \beta, \nu)$ in the first equality of (60) due to the space dependence of $\beta (\mathbf{r})$ there is some ambiguity in $p^\ell_m (\mathbf{r} | \beta, \nu)$ available to remove the inequality. This is due to the fact that only the space derivative of $t_{0ij}(\mathbf{r})$ occurs in (40). Consequently, any tensor of the form

$$\bar{t}^\ell_{0ij} (\mathbf{r}) = \tilde{t}_{0ij} (\mathbf{r}) + \epsilon_{jkn} \partial_k A_{ni} (\mathbf{r}) \hspace{1cm} (67)$$
will give an equivalent derivative. More generally, it is shown that the contour in the
definition of \( \mathcal{D}_j (r, q_1, q_2) \), (21) can be chosen such that \( t_{0ij}(r) = t_{oji}(r) \) (see Supporting
Information S.2), and hence
\[
\partial_j \overline{t_{0ij}} (r) = \partial_j \overline{t_{0ji}} (r). \tag{68}
\]

Then the generalization of (67) to its symmetric form is
\[
t'_0 \overline{ij} \ell (r) = t_0 \overline{ij} \ell (r) + \varepsilon_{ik\ell} \varepsilon_{jmn} \partial_k \partial_m A_\ell n, \quad A_\ell n = A_n \ell, \tag{69}
\]
where here \( t_0 \overline{ij} \ell \) is the symmetric form of Supporting Information S.2. It is readily verified that
\[
\partial_j t'_0 \overline{ij} \ell (r) = \partial_j t_0 \overline{ij} \ell (r) \quad \partial_i t'_0 \overline{ij} \ell (r) = \partial_i t_0 \overline{ij} \ell (r). \tag{70}
\]

The hydrodynamic pressure tensor associated with \( t'_0 \overline{ij} \ell (r, t) \) is
\[
p'_\ell \overline{ij} (r | \beta, \nu) \equiv t'_0 \overline{ij} \ell (r | \beta, \nu) = t_0 \overline{ij} \ell (r | \beta, \nu) + \varepsilon_{ik\ell} \varepsilon_{jmn} \partial_k \partial_m A_\ell n (r | \beta, \nu)
= p'_\ell \overline{ij} (r | \beta, \nu) + \varepsilon_{ik\ell} \varepsilon_{jmn} \partial_k \partial_m A_\ell n (r | \beta, \nu) \tag{71}
\]
and the corresponding pressure is
\[
p'_\ell (r | \beta, \nu) = p'_\ell (r | \beta, \nu) + \frac{1}{3} \varepsilon_{ik\ell} \varepsilon_{jmn} \partial_k \partial_m A_\ell n (r | \beta, \nu)
= p'_\ell (r | \beta, \nu) + \frac{1}{3} \left( \partial^2 A_\ell (r | \beta, \nu) - \partial_k \partial_\ell A_{k\ell} (r | \beta, \nu) \right). \tag{72}
\]

Use has been made of the identity
\[
\varepsilon_{ik\ell} \varepsilon_{jmn} = \delta_{km} \delta_{\ell n} - \delta_{kn} \delta_{\ell m}. \tag{73}
\]

To further simplify (72) choose the arbitrary tensor \( A_{k\ell} (r | \beta, \nu) \) to be diagonal
\[
A_{k\ell} (r | \beta, \nu) \rightarrow \delta_{k\ell} A (r | \beta, \nu), \tag{74}
\]
giving
\[
p'_\ell (r | \beta, \nu) = p'_\ell (r | \beta, \nu) + \frac{2}{3} \nabla^2 A (r | \beta, \nu), \tag{75}
p'_{ij} \ell (r | \beta, \nu) = p'_{ij} \ell (r | \beta, \nu) + \left( \delta_{ij} \nabla^2 - \partial_j \partial_i \right) A (r | \beta, \nu). \tag{76}
\]

It is now seen that the hydrodynamic pressure \( p'_\ell (r | \beta, \nu) \) can be equated to the thermodynamic pressure \( p'_0 (r | \beta, \nu) \) by the choice
\[
\frac{2}{3} \nabla^2 A(r \mid \beta, \nu) = -\Delta p^\ell_0 (r \mid \beta, \nu). 
\tag{77}
\]

Since \( \Delta p^\ell_0 (r \mid \beta, \nu) \) is given explicitly by \((62)\), this Poisson’s equation for \( A(r \mid \beta, \nu) \) is well-defined. In summary, by modifying the form for the average stress tensor the momentum balance equation is unchanged but the mechanical pressure can be chosen equal to the equilibrium pressure for both the equilibrium and local equilibrium states, and that pressure is \( p^\ell_0 (r \mid \beta, \nu) \) or \( p^\ell_0 (r, \beta \mid \nu) \) respectively.

As a special simple case the explicit results for a non-interacting inhomogeneous gas are
\[
\frac{2}{3} \nabla^2 A(r \mid \beta, \nu) = -\frac{\hbar^2}{12m} \nabla^2 \bar{n}^\ell (r), \tag{78}
\]
with the solution
\[
A(r \mid \beta, \nu) = -\frac{\hbar^2}{8m} \bar{n}^\ell (r) + a(r \mid \beta, \nu), \quad \nabla^2 a(r \mid \beta, \nu) = 0. \tag{79}
\]

In summary, by changing the form of the pressure tensor to \((71)\) there is the freedom to choose the new mechanical local pressure \( p^\ell_0 (r \mid \beta, \nu) \) to be equal to the thermodynamic local pressure \( p^\ell_0 (r \mid \beta, \nu) \). In this way the desired equality
\[
Q^\ell[\beta, \nu] = \int d\mathbf{r} \beta (\mathbf{r}) p^\ell_0 (\mathbf{r} \mid \beta, \nu) = \int d\mathbf{r} \beta (\mathbf{r}) p^\ell_m (\mathbf{r} \mid \beta, \nu), \tag{80}
\]
is recovered. This result holds for both equilibrium and local equilibrium states.

V. DISCUSSION

The definition of a local pressure from two conceptually different origins has been considered. The first is thermodynamic in nature, associated with the local density for the grand potential. The other is mechanical in nature, associated with the average of the local momentum flux (referred to as the mechanical or hydrodynamic pressure). First, a strictly equilibrium state for an inhomogeneous system was described. This is the case of interest for density functional theory where the task is to calculate the global free energy. Although local free energy densities are introduced in that context they are mainly for computational convenience. However, they also provide the basis for a local thermodynamics as well. For example, a local pressure follows from a local “Legendre transformation” of the free energy density\(^4\). In the present case, the thermodynamic local pressure is introduced directly as
the density for the grand potential. It is then compared to the pressure defined from the equilibrium average of the momentum flux (equilibrium force balance equation). The two are different for strongly inhomogeneous states. However, the possibility of adding a contribution \( \Delta p^\ell_0 (\mathbf{r} | \beta, \nu) \) whose volume integral vanishes to the grand potential density can be exploited to assure the thermodynamic and hydrodynamic local pressures are the same.

The same analysis for local equilibrium states, where the temperature is also non-uniform, again leads to different forms for the thermodynamic and hydrodynamic local pressures. But in this case there is no longer the flexibility to add a contribution \( \Delta p^\ell_0 (\mathbf{r} | \beta, \nu) \) to the thermodynamic local pressure for resolution. Instead, the hydrodynamic local pressure can be changed by exploiting the fact that the momentum flux occurs in the momentum conservation law only as a divergence of that flux. In this way agreement of the thermodynamic and hydrodynamic local pressures is restored.

For consistency between the local and strict equilibrium states in the limit of uniform temperature, the local equilibrium form must be used, \( p^\ell_0 (\mathbf{r} | \beta, \nu) = p^\ell_m (\mathbf{r} | \beta, \nu) \), i.e. the same average momentum flux should be adopted in each case. This is a somewhat simpler form than the pressure tensor and local pressure than \( p^\ell_m (\mathbf{r} | \beta, \nu) \) for the strict equilibrium case. The requirement that the force balance equation at local equilibrium gives the correct local density for the local equilibrium grand potential gives a strong constraint on the equilibrium form as well.

As noted in (59) both \( p^\ell_0 (\mathbf{r} | \beta, \nu) \) and \( p^\ell_m (\mathbf{r} | \beta, \nu) \) are the local densities for the global pressure, without any need for modification of the pressure tensor. If that were chosen to be the constraint of thermodynamic consistency, then no modification of the choice \( p^\ell_m (\mathbf{r} | \beta, \nu) = p^\ell (\mathbf{r} | \beta, \nu) \) as in the equilibrium case is required - no change in the pressure tensor. Agreement of the equilibrium and local equilibrium cases would be direct, but the inequality (60) would remain. The consequences of this for local equilibrium thermodynamics is not clear and needs to be explored further. The grand potential is a Massieu-Planck functional in the foundations of local equilibrium thermodynamics. The pressure functional alone has no corresponding role.

Reference has been made above to density functional theory where the pressure is expressed as a functional of the density \( n \) rather than the activity \( \nu \). This change of variables
is obtained by inverting
\[
\overline{n(\mathbf{r} \mid \beta, \nu)}^\ell = \overline{n}^\ell \quad \rightarrow \quad \nu = \nu(\mathbf{r} \mid \beta, n).
\] (81)

This is a difficult problem, separate from the discussion referring to the definition of \( p_0^\ell (\mathbf{r} \mid \beta, \nu) \). However, the proof that the hydrodynamic pressure can be chosen to be the same as the thermodynamic pressure assures that the tools of density functional theory can be used within the hydrodynamic context as well.

In closing it is useful to return to the extensive literature mentioned above regarding the definition of the pressure tensor and its measurement by molecular dynamics simulation\(^9,^{23-25}\), and its common implementation in the Sandia National Laboratories code LAMMPS (Large-scale Atomic/Molecular Massively Parallel Simulator). These simulations refer to methods for direct evaluation of the microscopic definitions of the various components for the pressure tensor. Here, no consideration is given for the pressure tensor components beyond its scalar trace. In that respect the equivalence constraint does not determine the full pressure tensor. Also, only its local equilibrium average is involved — the residual irreversible component of the momentum flux is not affected. A direct measurement of the momentum flux by simulation would give the total of both components (see eq.(47)), which would give the part studied here only for non-dissipative flows, e.g., the equilibrium state. Finally, the equivalence condition is the equality of two functionals of the density and temperature. The numerical confirmation of functional equivalence is indeed a formidable task. Thus the important simulation studies are only of indirect bearing on the limited scope considered here.

S.1. CONSERVATION OF NUMBER AND MOMENTUM DENSITIES

The dynamics of operators is defined by

$$\partial_t X(t) = i[H_N(t), X(t)],$$  \hspace{1cm} (S.1)

with the Hamiltonian given by

$$H_N(t) = H_N + \sum_{\alpha=1}^{N} v_{\text{ext}}(q_{\alpha}(t), t)),$$  \hspace{1cm} (S.2)

$$H_N(t) = \sum_{\alpha=1}^{N} \frac{p_{\alpha}^2(t)}{2m} + \frac{1}{2} \sum_{\alpha \neq \sigma=1}^{N} U_N(|q_{\alpha}(t) - q_{\sigma}(t)|).$$  \hspace{1cm} (S.3)

The operators corresponding to the number and momentum densities are

$$n(r, t) = \sum_{\alpha=1}^{N} \delta(r - q_{\alpha}(t)), \quad p(r, t) = \sum_{\alpha=1}^{N} \left[ \frac{p_{\alpha}^2(t)}{2m}, \delta(r - q_{\alpha}(t)) \right]_+.$$  \hspace{1cm} (S.4)

The brackets $[A, B]_+$ with a subscript $+$ denote an anti-commutator.

Local conservation laws follow exactly from this Hamiltonian dynamics. The simplest is the conservation of number density

$$\partial_t n(r, t) = i[H_N(t), n(r, t)] = \sum_{\alpha=1}^{N} i \left[ \frac{p_{\alpha}^2(t)}{2m}, \delta(r - q_{\alpha}(t)) \right]$$

$$= \sum_{\alpha=1}^{N} \left\{ \frac{p_{\alpha}^2(t)}{2m} \left[ \partial_{q_{\alpha}(t)} \delta(r - q_{\alpha}(t)) \right] \right. + \left. \partial_{q_{\alpha}(t)} \delta(r - q_{\alpha}(t)) \right\} \frac{p_{\alpha}^2(t)}{2m}$$

$$= \frac{1}{2m} \sum_{\alpha=1}^{N} \left( p_{\alpha}^2(t) \partial_{q_{\alpha}(t)} \delta(r - q_{\alpha}(t)) + \partial_{q_{\alpha}(t)} \delta(r - q_{\alpha}(t)) p_{\alpha}^2(t) \right)$$  \hspace{1cm} (S.5)

or, with the definition of $p(r)$ in (S.4), the microscopic continuity equation is obtained

$$\partial_t n(r, t) + \frac{1}{m} \nabla \cdot p(r, t) = 0.$$  \hspace{1cm} (S.6)
Use has been made of the property
\[ i [p_{\alpha j} (t), A (q_{\alpha} (t))] = \partial_{q_{\alpha j} (t)} A (q_{\alpha} (t)). \] (S.7)

The time derivative of \( p (r, t) \) follows in a similar way
\[
\partial_t p_j (r, t) = \frac{1}{2} \sum_{\alpha = 1}^N \left\{ [p_{\alpha j} (t), i [H_N (t), \delta (r - q_{\alpha} (t))]] + [i [H_N (t), p_{\alpha j} (t)], \delta (r - q_{\alpha} (t))]] \right\} + \frac{1}{2} \sum_{\alpha = 1}^N \left\{ [f_{\alpha j}^2 (t)] \delta (r - q_{\alpha} (t))\right\} + \frac{1}{2} \sum_{\alpha = 1}^N \left\{ [\partial_{q_{\alpha j} (t)} V^{\text{ext}} (q_{\alpha} (t), t)]\right\}
\]

where \( F_{\alpha j} (|q_{\alpha} (t) - q_{\beta} (t)|) \) is the \( j^{th} \) component of the force on particle \( \alpha \) due to particle \( \beta \)
\[ F_{\alpha j} (|q_{\alpha} - q_{\beta}|) = -\partial_{q_{\alpha j} (t)} V (|q_{\alpha} (t) - q_{\beta} (t)|), \] (S.9)
and \( F_{\alpha j}^{\text{ext}} (q_{\alpha} (t)) \) is the \( j^{th} \) component of the force on particle \( \alpha \) due to the external potential
\[ F_{\alpha j}^{\text{ext}} (q_{\alpha} (t)) = -\partial_{q_{\alpha j} (t)} u (q_{\alpha} (t), t). \] (S.10)

The last term on the right side of (S.8) can be rewritten as
\[
\sum_{\alpha \neq \beta = 1}^N F_{\alpha j} (|q_{\alpha} (t) - q_{\beta} (t)|) \delta (r - q_{\alpha} (t)) = \sum_{\alpha \neq \beta = 1}^N F_{\beta j} (|q_{\beta} (t) - q_{\alpha} (t)|) \delta (r - q_{\beta} (t))
\]

as follows from Newton’s third law. Therefore
\[
\sum_{\alpha \neq \beta = 1}^N F_{\alpha j} (|q_{\alpha} (t) - q_{\beta} (t)|) \delta (r - q_{\alpha} (t)) = \frac{1}{2} \sum_{\alpha \neq \beta = 1}^N F_{\alpha j} (|q_{\alpha} (t) - q_{\beta} (t)|) \times (\delta (r - q_{\alpha} (t)) - \delta (r - q_{\beta} (t))).
\] (S.12)

Next note the identity
\[ \delta (r - q_1) - \delta (r - q_2) = \int_{\lambda_2}^{\lambda_1} d\lambda \frac{d}{d\lambda} \delta (r - x (\lambda)), \quad x (\lambda_1) = q_1, \quad x (\lambda_2) = q_2. \] (S.13)

Here \( x (\lambda) \) is an arbitrary path for the vector \( x \) moving from \( x (\lambda_2) = q_2 \) to \( x (\lambda_1) = q_1 \). Carrying out the derivative gives
\[ \delta (r - q_1) - \delta (r - q_2) = -\partial_r D_k (r, q_1, q_2). \] (S.14)
where

\[ D_k (r, q_1, q_2) = \int_{\lambda_2}^{\lambda_1} d\lambda \frac{dx_k (\lambda)}{d\lambda} \delta (r - x (\lambda)). \] (S.15)

Use of (S.14) in (S.12) and (S.8) gives the momentum conservation law

\[ \partial_t p_j (r, t) + \partial_{r_i} t_{jk} (r, t) = f_j (r, t) \] (S.16)

where the total momentum flux \( t_{\alpha\beta} (r, t) \) is the sum of a kinetic and potential part

\[ t_{\alpha\beta} (r, t) = t_{\alpha\beta}^K (r, t) + t_{\alpha\beta}^P (r, t), \] (S.17)

\[ t_{jk}^K (r, t) = \frac{1}{4m} \sum_{\alpha=1}^{N} \left[ p_{\alpha j} (t), [p_{\alpha k} (t), \delta (r - q_\alpha (t))] \right]_+, \] (S.18)

\[ t_{jk}^P (r, t) = \frac{1}{4} \sum_{\alpha \neq \beta=1}^{N} F_{\alpha j\beta} ([q_\alpha (t) - q_\beta (t)]) D_k (r, q_\alpha (t), q_\beta (t)). \] (S.19)

The right side of (S.16) is the force density of the external potential

\[ f_j (r, t) = \sum_{\alpha=1}^{N} \delta (r - q_\alpha (t)) F_{\alpha j}^{\text{ext}} (q_\alpha (t)). \] (S.20)

### S.2. Determination of Momentum Flux

The straightforward derivation of the momentum conservation law in Appendix S.1 leads to a momentum flux (as in the text the dependence on \( t \) will be left implicit as it plays no role in the following)

\[ t_{ij} (r) = \frac{1}{4m} \sum_{\alpha=1}^{N} \left[ p_{i\alpha}, [p_{j\alpha}, \delta (r - q_\alpha)] \right]_+ + \frac{1}{2} \sum_{\alpha \neq \sigma=1}^{N} F_{\alpha i\sigma} ([q_\alpha - q_\sigma]) D_j (r, q_\alpha, q_\sigma), \] (S.21)

where the operator \( D_j (r, q_\alpha, q_\sigma) \) is given by

\[ D_j (r, q_1, q_2) \equiv \int_{C} d\lambda \frac{dx_j (\lambda)}{d\lambda} \delta (r - x (\lambda)), \quad x(\lambda_1) = q_1, \quad x(\lambda_2) = q_2. \] (S.22)

Here \( C \) is an arbitrary continuous path connecting \( x (\lambda) \) between \( \lambda_1 \) and \( \lambda_2 \). Consider the simplest choice a linear path

\[ x (\lambda) = q_1 + (q_2 - q_1) \lambda. \] (S.23)

Then

\[ D_j (r, q_1, q_2) \rightarrow (q_{2j} - q_{1j}) \int_{0}^{1} d\lambda \delta (r - q_1 - (q_2 - q_1)\lambda), \quad x(\lambda_1) = q_1, \quad x(\lambda_2) = q_2. \] (S.24)

Since \( F_{\alpha i\sigma} ([q_\alpha - q_\sigma]) \propto (q_{2i} - q_{1i}) \) use of (S.24) in (S.21) leads to a form for the momentum flux that is symmetric, \( t_{ij} (r) = t_{ji} (r) \), and consequently its divergence with respect to first and second indices are the same

\[ \partial_j t_{ij} (r) = \partial_j t_{ji} (r). \] (S.25)
Next define another symmetric momentum flux whose divergences are the same as those of \( \text{(S.25)} \)

\[
t_{ij}'(\mathbf{r}) = t_{ij}(\mathbf{r}) + \epsilon_{ikl} \epsilon_{jmn} \partial_k \partial_m A_{\ell n}(\mathbf{r}),
\]

(S.26)

for some unspecified tensor field \( A_{\ell n}(\mathbf{r}) \) and \( \epsilon_{ikl} \) is the Levi-Cevita tensor. This added term is seen to be the curl of a vector associated with each component of \( t_{ij}(\mathbf{r}) \) (i.e., noting that \( t_{ij}(\mathbf{r}) \) transforms as vector for components \( i \) at fixed \( j \), and vice versa). With the additional condition \( A_{\ell n}(\mathbf{r}) = A_{nl}(\mathbf{r}) \), it is verified that

\[
t_{ij}'(\mathbf{r}) = t_{ji}'(\mathbf{r}),
\]

(S.27)

\[
\partial_j t_{ij}'(\mathbf{r}) = \partial_j t_{ji}'(\mathbf{r}).
\]

(S.28)

The two indefinite features of the momentum flux have now been made explicit with the contour fixed by symmetry and the choice of a term with vanishing divergence. It is interesting to note that the contribution from different contours, denoted by \( \Delta D_j(\mathbf{r}, q_1, q_2) \) has a vanishing divergence, since the endpoints of the integration in \( \text{(S.24)} \) are the same for all contours. Consequently, the divergence of \( \Delta D_j \) vanishes, \( \partial_j \Delta D_j = 0 \). It follows that \( \Delta D_j \) is the curl of some vector. Hence, the difference between contours is included in the form \( \text{(S.26)} \).

### S.3. PERCUS PRESSURE TENSOR

The free energy is obtained from the grand potential by a Legendre transform

\[
\beta F(\beta, V | \overline{\pi}) = -Q^\circ(\beta, V | \nu) + \int d\mathbf{r} \overline{\pi}(\mathbf{r}) \nu(\mathbf{r})
\]

(S.29)

where \( \overline{\pi}(\mathbf{r}) = \langle n(\mathbf{r}) \rangle \) is the average number density. The free energy and grand potential are expressed as integrals of their respective densities

\[
F(\beta, V | \overline{\pi}) = \int d\mathbf{r} f(\mathbf{r}, \beta | \overline{\pi}), \quad Q^\circ(\beta, V | \nu) = \int d\mathbf{r} \beta p_T(\mathbf{r}, \beta | \nu)
\]

(S.30)

so that

\[
\beta p_T(\mathbf{r}, \beta | \nu) = \overline{\pi}(\mathbf{r}) \nu(\mathbf{r}) - f(\mathbf{r}, \beta | \overline{\pi}).
\]

(S.31)

The Percus pressure tensor \( \text{S.22} \) is defined by

\[
p_{ij}(\mathbf{r}, \beta | \overline{\pi}) = \delta_{ij} \beta p_T(\mathbf{r}, \beta | \nu) + \frac{1}{3} \int d\mathbf{r}' \int_0^1 d\gamma \frac{\delta f(\mathbf{r} + \gamma \mathbf{r}' - \mathbf{r}', \beta | \overline{\pi})}{\delta \overline{\pi}(\mathbf{r} + \gamma \mathbf{r}')} \partial_j \overline{\pi}(\mathbf{r} + \gamma \mathbf{r}').
\]

(S.32)

The corresponding mechanical pressure is

\[
p_m(\mathbf{r}, \beta | \overline{\pi}) = p_T(\mathbf{r}, \beta | \nu) + \frac{1}{3} \int d\mathbf{r}' \int_0^1 d\gamma \frac{\delta f(\mathbf{r} + \gamma \mathbf{r}' - \mathbf{r}', \beta | \overline{\pi})}{\delta \overline{\pi}(\mathbf{r} + \gamma \mathbf{r}')} r'_i \partial_i \overline{\pi}(\mathbf{r} + \gamma \mathbf{r}').
\]

(S.33)

No motivation nor interpretation for this result is provided.

First, prove the force balance equation. Separate the pressure tensor into two parts

\[
p_{ij}(\mathbf{r}, \beta | \overline{\pi}) = \delta_{ij} \beta p_T(\mathbf{r}, \beta | \overline{\pi}) + \Delta P_{ij}(\mathbf{r}, \beta | \overline{\pi}),
\]

(S.34)

\[
\Delta P_{ij}(\mathbf{r}, \beta | \overline{\pi}) = \int d\mathbf{r}' r_i' \int_0^1 d\gamma \frac{\delta f(\mathbf{r} + \gamma \mathbf{r}' - \mathbf{r}', \beta | \overline{\pi})}{\delta \overline{\pi}(\mathbf{r} + \gamma \mathbf{r}')} \partial_j \overline{\pi}(\mathbf{r} + \gamma \mathbf{r}').
\]

Then

\[
\delta_{ij} \partial_i \beta p_T(\mathbf{r}, \beta | \overline{\pi}) = \delta_{ij} \partial_i (\overline{\pi}(\mathbf{r}) \nu(\mathbf{r}) - \beta f(\mathbf{r}, \beta | \overline{\pi})) = \overline{\pi}(\mathbf{r}) \partial_j \nu(\mathbf{r}) + \nu(\mathbf{r}) \partial_j \overline{\pi}(\mathbf{r}) - \partial_j \beta f(\mathbf{r}, \beta | \overline{\pi})
\]

(S.35)
and
\[ \partial_i \Delta p_{ij} (r, \beta \mid \bar{\pi}) = \int dr' r'_i \partial_i \int_0^1 d\gamma \frac{\delta \beta f (r + \gamma r' - r', \beta \mid \bar{\pi})}{\delta \bar{\pi}(r + \gamma r')} \partial_j \bar{\pi}(r + \gamma r') \]
\[ = \int dr' \int_0^1 d\gamma \partial_i \left( \frac{\delta \beta f (r + \gamma r' - r', \beta \mid \bar{\pi})}{\delta \bar{\pi}(r + \gamma r')} \partial_j \bar{\pi}(r + \gamma r') \right) \]
\[ = \int dr' \left( \frac{\delta \beta f (r, \beta \mid \bar{\pi})}{\delta \bar{\pi}(r + r')} \partial_j \bar{\pi}(r + r') - \frac{\delta \beta f (r - r', \beta \mid \bar{\pi})}{\delta \bar{\pi}(r)} \partial_j \bar{\pi}(r) \right) \]
\[ = \int dr' \frac{\delta \beta f (r, \beta \mid \bar{\pi})}{\delta \bar{\pi}(r_1)} \partial_j \bar{\pi}(r_1) - \frac{\delta \beta F (\beta \mid \bar{\pi})}{\delta \bar{\pi}(r)} \partial_j \bar{\pi}(r) \]
\[ = - (\nu(r) \partial_j \bar{\pi}(r) - \partial_j \beta f (r, \beta \mid \bar{\pi})) \tag{S.36} \]
so the force balance equation is verified
\[ \partial_i \beta p_{ij} (r, \beta \mid \bar{\pi}) = \bar{\pi}(r) \partial_j \nu(r). \tag{S.37} \]

For the pressure to qualify as a thermodynamic pressure it should satisfy
\[ \int dr \beta p_m (r, \beta \mid \nu) = Q^c (\beta, V \mid \nu). \tag{S.38} \]

Use of the Percus form \( \text{(S.33)} \) gives this condition to be
\[ \int dr \frac{1}{3} \int dr' \int_0^1 d\gamma \frac{\delta f (r + \gamma r' - r', \beta \mid \bar{\pi})}{\delta \bar{\pi}(r + \gamma r')} \bar{\pi}' \partial_i \bar{\pi}(r + \gamma r') = 0. \tag{S.39} \]
The Appendix of Ref. \textit{S3} claims that this is true, but no proof is given.
